Abbreviations, diagnostic guidelines
Hemophilia (HL): definition 1
HL is a group of a sex-linked hereditary genetic disorders that occurs almost exclusively in males and impairs the body's ability to control blood clotting, which is used to stop bleeding when a blood vessel is broken even after minor injuries
Types:
• HL A (clotting factor VIII deficiency) is a recessive X-linked most common form of the disorder which occurs in 1 in 5,000–10,000 male births

Hemophilia (HL): definition 2

HL is a group of a sex-linked hereditary genetic disorders that occurs almost exclusively in males and impairs the body's ability to control blood clotting, which is used to stop bleeding when a blood vessel is broken even after minor injuries.

Types:

• HL B (factor IX deficiency) is a recessive X-linked form of the disorder which occurs in 1 in 20,000–34,000 male births.

Hemophilia (HL): definition 3

HL is a group of a sex-linked hereditary genetic disorders that occurs almost exclusively in males and impairs the body's ability to control blood clotting, which is used to stop bleeding when a blood vessel is broken even after minor injuries.

Types:

- HL C or plasma thromboplastin antecedent (PTA) deficiency or Rosenthal syndrome (factor XI deficiency) is an autosomal (i.e. not X-linked) genetic disorder which occurs in both sexes.
Hemophilia (HL): epidemiology

Global distribution of bleeding disorders (a) and HL A (c) in five countries reporting the highest number of patients (b) and (d) show s that nearly 5 and 9% of global patients with bleeding disorders and HL A are from India.
Hemophilia (HL): epidemiology

Distribution by age for patients with HL A&B

Hemophilia (HL): risk factors and etiology

- Risk factors for HL include family history of bleeding and almost always being male.
- HL is caused by an inherited X-linked recessive trait, with the defective gene located on the X chromosome.
- Males have only one X chromosome, and if the factor VIII gene or if the factor IX gene is missing on a boy's X chromosome, he will have HL A or HL B.

http://emedicine.medscape.com/article/955690-overview
Hemophilia (HL): risk factors and etiology 2

- If a woman has a defective factor VIII gene or a defective factor IX gene, she is considered a carrier: boys born to such women have a 50% chance of having hemophilia A or hemophilia B, and their daughters have a 50% chance of being a carrier.
Hemophilia (HL): risk factors and etiology 3

• HL C with deficiency of factor XI was described first in 2 sisters and a maternal uncle of an American Jewish family after bled from dental extractions; unlike the bleeding tendency in HL A or HL B, which is clearly related to the factor level, the bleeding risk in HL C is not always influenced by the severity of the deficiency, especially in individuals with partial deficiency.

• All female children of men with HL carry the defective gene.

http://emedicine.medscape.com/article/955690-overview
Hemophilia (HL): risk factors and etiology

When the mother carries the haemophilia gene and the father is unaffected:

- Father: XY
- Mother: XX

There is a 50% chance at each birth that a son will have haemophilia.

There is a 50% chance at each birth that a daughter will carry the haemophilia gene.

When the father has haemophilia and the mother is unaffected:

- Father: XY
- Mother: XX

None of the sons will have haemophilia.

All of the daughters will carry the haemophilia gene.

Normal blood clotting is a complex process requiring as many as 20 clotting factors. The deficiency or absence of one of these factors may disrupt the clotting process.
Hemophilia (HL): mechanisms 2

Diagram showing how in hemophilia patients, blood cannot clot properly because of poor platelet plug.
Hemophilia (HL): clinical presentation 1

• All symptom of HL are related to uncontrolled or unexpected bleeding, either externally (e.g. skin cut, nosebleed) or internally (e.g. knee, muscle, brain)
• The extent of bleeding depends on the amount of functional clotting factors present in the body; when the amount of clotting factor is low, bleeding symptoms become more severe
• Internal bleeding into the joints, muscle and brain is serious and requires immediate medical attention
• The following bleeding symptoms are associated with HL:
  • Excessive bleeding following minor injuries (e.g. skin cut)
  • Large skin bruises from bleeding within the skin
  • Uncontrolled bleeding after receiving a shot or pulling a tooth
  • Frequent nosebleeds that are hard to stop
  • Blood in the urine or stool
  • Pain and swelling in the joints due to internal bleeding
  • Infantile bleeding after birth or circumcision
  • Headaches and difficulties with vision

http://www.innerbody.com/diseases-conditions/hemophilia
Hemophilia (HL): severity classification

- HL is classified as mild, moderate, or severe depending on the amount of the clotting factor present in a person’s blood.
- The normal range of FVIII and FIX is between 50% and 150%.

Hemophilia (HL): severity classification

• Mild: bleeding occur after injury, trauma, or surgery; the condition may have very few symptoms otherwise - 25% of the HL population
• Moderate: bleeding episodes tend to occur after minor injuries, spontaneous bleeding episodes may occur - 15% of the HL population
• Severe: in addition to bleeding after injury, trauma, or surgery, severe hemophilia characterized by spontaneous bleeding into joints and muscles - 60% of the HL population

Hemophilia (HL): severity classification

Hemophilia (HL): clinical presentation 2

Frequency and sites of bleeding in patients with severe and moderate HL A

http://www.ijmr.org.in/article.asp?issn=0971-5916;year=2014;volume=140;issue=1;spage=19;epage=31;aulast=Kar
Hemophilia (HL): clinical presentation 3

- Bleeding may occur anywhere in the body
- The most serious sites of bleeding are joints, muscles, digestive tract and brain
- Muscle and joint haemorrhages (hemaarthrosis) are indicative of hemophilia, while digestive tract and cerebral haemorrhages are also germane to other coagulation disorders
- Though typically not life-threatening, joint bleeds are one of the most serious symptoms of HL

https://en.wikipedia.org/wiki/Haemophilia
Hemophilia (HL): clinical presentation 4

• Repeated bleeds into a joint capsule can cause permanent joint damage and disfigurement resulting in chronic arthritis and disability

• Joint damage is not a result of blood in the capsule but rather the healing process

• When blood in the joint is broken down by enzymes in the body, the bone in that area is also degraded

https://en.wikipedia.org/wiki/Haemophilia

[Symptoms, Topic and Severity of HL](http://www.ihtc.org/medical-professionals/blood-disorders/bleeding-disorders/hemophilia-a-and-b/)

Hemophilia (HL): complications 1

Complications may be both directly from the disease or from its treatment:

- Deep internal bleeding, e.g. deep-muscle bleeding, leading to swelling, numbness or pain of a limb
- Joint damage from hemarthrosis (hemophilic arthropathy), potentially with severe pain, disfigurement, and even destruction of the joint and development of debilitating arthritis

https://en.wikipedia.org/wiki/Haemophilia
Hemophilia (HL): complications 2

- Transfusion transmitted infection from blood transfusions that are given as treatment
- Adverse reactions to clotting factor treatment, including the development of an immune inhibitor which renders factor replacement less effective
- Intracranial hemorrhage is a serious medical emergency caused by the buildup of pressure inside the skull, that can cause disorientation, nausea, loss of consciousness, brain damage, and death

https://en.wikipedia.org/wiki/Haemophilia
Hemophilia (HL): complications

HL bleedings
Hemophilia (HL): diagnosis 1

- Personal history of bleeding
- Family history of bleeding and its inheritance pattern
- Laboratory evaluation
- Genetic testing to determine an individual's risk of attaining or passing on HL
Hemophilia (HL): diagnosis 2

Laboratory Evaluation

• In a patient with suspected HL, screening coagulation tests along with mixing studies are performed
• The activated partial thromboplastin time (aPTT) assay evaluates the intrinsic pathway of coagulation and is quite often prolonged in patients with HL
• If the aPTT is prolonged, a mixing study is performed to evaluate the correction of a patient’s aPTT with a pooled plasma from healthy donors
• In patients with coagulation factor deficiencies, the aPTT is corrected in a 1:1 mixing study
• If a factor deficiency is suspected, then specific factor assays such as FVIII and FIX levels are performed to diagnose the type and severity of the deficiency
• In patients with mild hemophilia, the aPTT assay may be normal
• Once the diagnosis of HL is established, the screening of other at-risk family members, including females, should be performed to diagnose other affected individuals and determine the clotting factor level of carriers

Hemophilia (HL): treatment 1

- Treatment is comprehensive and focused on preserving both physical health and quality of life of individuals with the disorder.
- The primary goal of treatment is the prevention or cessation of bleeding episodes.
- Prompt treatment of acute bleeding episodes is essential to minimize long-term complications.
- Both nonpharmacologic and pharmacologic strategies are used in the treatment.

Hemophilia (HL): treatment 2

Nonpharmacologic therapy consists of supportive care

- Rest, ice, compression, and elevation (RICE) are important measures for treatment of joint or muscle bleeding episodes
- Splints, crutches, or casts can be used to allow the affected joint or muscle to rest after a bleeding episode
- Cold or ice compresses should be applied for 20 minutes every 4 to 6 hours
Hemophilia (HL): treatment 3

Pharmacologic strategies

• HL can be controlled with regular infusions of the deficient clotting factor (VIII in HL A or IX in HL B)
• Some patients develop antibodies against the replacement factors, so them non-human products must be given, such as porcine factor VIII
• If a patient becomes refractory to replacement coagulation factor, this may be partially overcome with recombinant human factor VII
Hemophilia (HL): treatment 4

Treatment regimens

- Optimal therapy for patients with severe HL A or B involves regular administration of clotting factor concentrates, often 2 to 3 times per week, to increase the factor level to a moderate range (> 1%) to prevent bleeding.

- Episodic Infusion (on-demand) treatment is defined as utilization of clotting factor concentrates in response to an acute bleeding episode to stop bleeding after it has started.

http://www.ihtc.org/medical-professionals/blood-disorders/bleeding-disorders/hemophilia-a-and-b
Hemophilia (HL):
treatment 5

New approaches (gene therapy)

• On 10 December 2011, a team of British and American investigators reported the successful treatment of HL B using gene therapy; they inserted the $F9$ gene into an adeno-associated virus-8 vector, which has a propensity for the liver, where factor 9 is produced, and remains outside the chromosomes so as not to disrupt other genes; the transduced virus was infused intravenously; to prevent rejection, the patients were primed with steroids to suppress their immune response

https://en.wikipedia.org/wiki/Haemophilia
Hemophilia (HL): treatment 6

New approaches (gene therapy)

• In October 2013, the Royal Free London National Health Society Foundation Trust in London reported that after treating six people with HL in early 2011 with the genetically modified adeno-associated virus, over two years later all were still producing blood plasma clotting factor

https://en.wikipedia.org/wiki/Haemophilia
Hemophilia (HL): treatment 7

Contraindication

- Anticoagulants and nonsteroidal antinflammatory drugs are contraindicated for people with HL as these can aggravate clotting difficulties
- Contraindicated are activities with a high likelihood of trauma, such as motorcycling and skateboarding, American football, hockey, boxing, wrestling, rugby, soccer, baseball, and basketball

https://en.wikipedia.org/wiki/Haemophilia
Hemophilia (HL): prognosis

• People with severe HL who don't receive adequate, modern treatment have greatly shortened lifespans and often do not reach maturity

• Prior to the 1960s average life expectancy was only 11 years

• By the 1980s average life expectancy was was 50–60 years

• Today with appropriate treatment an average lifespan in people with severe HL is approximately 10 years shorter than an unaffected people

https://en.wikipedia.org/wiki/Haemophilia
Hemophilia (HL): prophylaxis

Patients are advised to

• Stay up-to-date on vaccinations
• Attend annual comprehensive clinic evaluations
• Avoid situations and activities that cause bleeding
• Maintain good oral hygiene (to prevent extensive dental procedures)
• Exercise regularly and maintain a healthy body weight

Hemophilia (HL): abbreviations

- **ACS** - acute coronary syndrome
- **aPCC** - activated prothrombin complex
- **aPTT** - activated partial thromboplastin time
- **ITI** - immune tolerance induction
- **HL** - Hemophilia
- **NS** - nephrotic syndrome
- **PCI** - percutaneous coronary intervention
- **pPTA** - plasma thromboplastin antecedent
- **rFVIIa** - recombinant activated Factor VII
Hemophilia (HL): diagnostic and treatment guidelines

2. thrombocytopenic purpura (TP)

Definition
Epidemiology, classification
Risk factors, etiology
Mechanisms, classification
Clinical presentation
Complications, diagnosis, treatment
Prognosis, prophylaxis
Abbreviations, diagnostic guidelines

Thrombocytopenic purpura (TP): definition

Thrombocytopenic purpura (TP) is purpura associated with a reduction in circulating blood platelets which can result from a variety of causes.
Thrombocytopenic purpura (TP): types 1

Type 1

- Immune TP (primary immune thrombocytopenia, primary immune TP or autoimmune TP), in most cases is immune-mediated and is defined as isolated low platelet count with normal bone marrow
Thrombocytopenic purpura (TP): types 2

Type 2

- Thrombotic TP (acquired - Moschcowitz syndrome, genetically inherited - Upshaw–Schulman syndrome), is a rare disorder of the blood-coagulation system, arising from inhibition or dysfunction of the enzyme ADAMTS13, and causing extensive microscopic clots (thrombi) to form in the small blood vessels throughout the body.
Thrombocytopenic purpura (TP): epidemiology

- The incidence of Immune TP is estimated at 50–100 new cases per million people per year, with children accounting for half of that amount.

- At least 70% of childhood cases will end up in remission within six months, even without treatment.

- A third of the remaining chronic cases will usually remit during follow-up observation, and another third will end up with only mild thrombocytopenia (defined as a platelet count above 50,000).

Thrombocytopenic purpura (TP): epidemiology

• Immune TP is usually chronic in adults and the probability of durable remission is 20–40%
• The male to female ratio in the adult group varies from 1:1.2 to 1.7
• The mortality rate due to chronic Immune TP varies but tends to be higher relative to the general population for any age range
• No significant difference was noted in the rate of survival between males and females

Thrombocytopenic purpura (TP): epidemiology

- The incidence of Thrombotic TP is about 4-5 cases per million people per year.
- Idiopathic Thrombotic TP occurs more often in women and people of African descent.
- Thrombotic TP secondary to autoimmune disorders occurs more frequently in people of African descent.
- Untreated, Thrombotic TP has a mortality rate of as high as 90%.

https://en.wikipedia.org/wiki/Thrombotic_thrombocytopenic_purpura#Unknown_cause
http://emedicine.medscape.com/article/206598-overview#as6
Thrombocytopenic purpura (TP): epidemiology 4

• With plasma exchange, the mortality rate is reduced to 10-20%
• Acute morbidities include ischemic events such as stroke, transient ischemic attacks, myocardial infarction and arrhythmia, bleeding, and azotemia
• TTP during pregnancy may precipitate fetal loss
• Relapses are not uncommon, occurring in 13-36% of patients

Thrombocytopenic purpura (TP): epidemiology 3

Immune TP incidence rates according to age and sex
Thrombocytopenic purpura (TP):

risk factors and etiology

1

Immune TP

• The acute form often follows an infection and has a spontaneous resolution within 2 months

• The chronic form persists longer than 6 months with a specific cause being unknown

• Immune TP can be triggered by drugs, or associated with infection, pregnancy, or immune disorders such as systemic lupus erythematosus, but about half of all cases are classified as "idiopathic," meaning the cause is unknown
Thrombocytopenic purpura (TP): risk factors and etiology 2

Thrombotic TP

- Acquired forms arise from inhibition of the enzyme ADAMTS13, a metalloprotease responsible for cleaving large multimers of von Willebrand factor (vWF) into smaller units with increased platelet adhesion to areas of endothelial injury.

- Genetically inherited form arising from dysfunction of ADAMTS13 with tendency for increased coagulation exists.

References:
Thrombocytopenic purpura (TP): mechanisms 1

Immune TP

• In 60% of cases, antibodies against platelet membrane glycoproteins IIb-IIIa or Ib-IX and the immunoglobulin G (IgG) type can be detected.

• The coating of platelets with IgG renders them susceptible to opsonization and phagocytosis by splenic macrophages, as well by Kupffer cells in the liver.

• The IgG autoantibodies are also thought to damage megakaryocytes.
Thrombocytopenic purpura (TP): mechanisms 2

Thrombotic TP

• Thrombotic TP is characterized by clotting in small blood vessels, resulting in a low platelet count

• In its full-blown form, the disease consists of the pentad of microangiopathic hemolytic anemia, thrombocytopenic purpura, neurologic abnormalities, fever, and renal disease

• Reduced blood flow due to thrombosis and cellular injury results in end organ damage
Thrombocytopenic purpura (TP): mechanisms 3

Mechanism of platelet destruction in Immune TP

Thrombocytopenic purpura (TP): mechanisms

Mechanisms of virus-induced thrombocytopenia
Thrombocytopenic purpura (TP): clinical presentation 1

Immune TP

• Bruising, petechiae, purpura
• Prolonged bleeding from cuts
• Spontaneous bleeding from nose
• Bleeding gums, especially after dental work
• Blood in urine or stools
• Unusually heavy menstrual flow
• Fatigue

Thrombocytopenic purpura (TP): clinical presentation 2

Thrombotic TP

- Bruising, petechiae, purpura, mucosal bleeding
- Microangiopathic hemolytic anemia
- Neurologic symptoms (hallucinations, bizarre behavior, delirium, stroke, hemiplegia, paresthesias, visual disturbance, aphasia, headaches)
- Kidney failure
- Fever

Thrombocytopenic purpura (TP): clinical presentation

Petechiae and purpura in the skin

Thrombocytopenic purpura (TP): diagnosis 1

Immune TP

• The diagnosis is a process of exclusion and has to be determined that there are no blood abnormalities other than a low platelet count, and no physical signs other than bleeding; secondary causes should be excluded

• Bone marrow examination is done if blood counts or blood smear reveals abnormalities in addition to thrombocytopenia, when clinical features are not typical, or if patients fail to respond to standard therapies
Thrombocytopenic purpura (TP): diagnosis

Thrombotic TP

- Measuring ADAMTS13 activity level
- Laboratory studies: complete blood count and total white blood cell count is normal or slightly elevated, hemoglobin concentration is moderately depressed at 8-9 g/dL, platelet count generally ranges from 20,000-50,000/μL; coagulation studies, blood urea nitrogen, creatinine, serum bilirubin and lactate dehydrogenase as indirect measures of the degree of hemolysis
Thrombocytopenic purpura (TP): treatment 1

Immune TP 1

- There is no need to treat based on platelet counts
- Current guidelines recommend treatment only in cases of significant bleeding
- Initial treatment consists of corticosteroids, the dose and mode of administration is determined by platelet count and whether there is active bleeding
- In chronic refractory cases, immunosuppressants (mycophenolate mofetil and azathioprine) and chemotherapy (vincristine) agent may be attempted

Thrombocytopenic purpura (TP): treatment 1

Immune TP 2

- Anti-RhD therapy for patients with certain blood types
- Infusions of high-dose gamma globulin
- Thrombopoietin receptor agonists (romiplostim, eltrombopag) that stimulate the bone marrow to make more platelets
- Platelet transfusion is recommended in an emergency

https://en.wikipedia.org/wiki/Idiopathic_thrombocytopenic_purpura#Treatment
https://en.wikipedia.org/wiki/Thrombotic_thrombocytopenic_purpura#Unknown_cause
Thrombocytopenic purpura (TP): treatment 2

Thrombotic TP

• The therapy of choice is plasma exchange with fresh frozen plasma

• Another option, is intravenous administration of octaplas, a sterile, frozen solution of pooled human plasma from several donors as alternative to single-donor plasma

• Corticosteroids may also be used in refractory patients

Thrombocytopenic purpura (TP): prognosis 1

Immune TP

- With treatment, the chance of remission (a symptom-free period) is good
- In rare cases, disease may become a long-term condition in adults and reappear, even after a symptom-free period

Thrombocytopenic purpura (TP): prognosis 2

Thrombotic TP

- The mortality rate is around 95% for untreated cases, but the prognosis is reasonably favorable (80–90% survival) for patients diagnosed and treated early with plasmapheresis.

Thrombocytopenic purpura (TP): prophylaxis

• There is no known way to prevent Immune TP and Thrombotic TP

Thrombocytopenic purpura (TP): abbreviations

- CBC - complete blood count
- IFA - interferon-alpha
- HIV - human immunodeficiency virus
- RA - rheumatoid arthritis
- SLE - systemic lupus erythematosus
- TP - thrombocytopenic purpura
- vWF - von Willebrand factor
