SIGNS AND SYMPTOMS OF CARDIOVASCULAR SYSTEM DISEASES
(syndromes of acquired heart defects)

LECTURE IN INTERNAL MEDICINE PROPAEDEUTICS

M. Yabluchansky, L. Bogun, L. Martymianova, O. Bychkova, N. Lysenko
V.N. Karazin National University Medical School’ Internal Medicine Dept.
Plan of the lecture

Acquired valvular heart defects
• Common data
• Aortic valve stenosis
• Aortic valve insufficiency/regurgitation
• Mitral valve stenosis
• Mitral valve insufficiency/regurgitation
Heart valves
Definition

- The heart valves are part of the dense connective tissue makeup of the heart known as the heart skeleton.
- Valves that are formed properly at birth can still develop problems in form of acquired valvular heart defects that may involve one or more of the four valves of the heart (the aortic and mitral valves on the left and the pulmonary and tricuspid valves on the right).

Classification

• The two major types defects of everyone heart valve are:
  – Insufficiency/regurgitation (the valve’s tissue flaps (leaflets), which control the flow and direction of the blood, do not fully close or the edges do not fully meet, which causes blood to leak back into the heart)
  – Stenosis (the leaflets cannot open fully to allow enough blood to flow through)
Causes and risk factors

- Age
- Heart attack
- Heredity
- Calcium deposits
- Endocarditis
- Rheumatic fever
- High blood pressure
- Cardiomyopathy
- Connective tissue diseases

Calcified aortic valves

[Link to more information](http://secondscount.org/heart-condition-centers/info-detail-2/types-causes-of-heart-valve-problems-2#.VcNQwCbtmko)
Common symptoms

- Shortness of breath
- Weakness
- Dizziness
- Discomfort in chest
- Palpitations
- Edema
Aortic valve stenosis
Aortic stenosis is the obstruction of blood flow across the aortic valve.
Classification

Aortic valve stenosis can be classified according to the anatomical location: supravalvular, valvular and subvalvular.
Causes

The causes of aortic valve disease include bicuspid aortic valve, degenerative aortic valve disease, rheumatic heart disease, atherosclerotic aortic disease, etc.

Bicuspid aortic valve
Risk factors are closely associated with atherosclerosis including diabetes, smoking, hypertension and dyslipidemia.
Pathophysiology

• When the aortic valve becomes stenotic, resistance to systolic ejection occurs and a systolic pressure gradient develops between the left ventricle and the aorta.

• This outflow obstruction leads to an increase in left ventricular (LV) systolic pressure.

• As a compensatory mechanism to normalize LV wall stress, LV wall thickness increases by parallel replication of sarcomeres, producing concentric hypertrophy.
At this stage, the chamber is not dilated and ventricular function is preserved, although diastolic compliance is reduced.

Eventually, LV end-diastolic pressure (LVEDP) rises, which causes an increase in pulmonary capillary arterial pressures and a decrease in cardiac output due to diastolic dysfunction.

The contractility of the myocardium may also diminish, which leads to a decrease in cardiac output due to systolic dysfunction.

Ultimately, heart failure develops.
In most patients, LV systolic function is preserved and cardiac output is maintained for many years despite an elevated LV systolic pressure.

Although cardiac output is normal at rest, it often fails to increase appropriately during exercise, which may result in exercise-induced symptoms.

Diastolic dysfunction may occur as a consequence of impaired LV relaxation and/or decreased LV compliance, as a result of increased afterload, LV hypertrophy, or myocardial ischemia.
Pathophysiology 4

• LV hypertrophy often regresses following relief of valvular obstruction

• Some individuals develop extensive myocardial fibrosis, which may not resolve despite regression of hypertrophy

• In patients with severe stenosis, atrial contraction plays a particularly important role in diastolic filling of the LV with development of atrial fibrillation often leads to heart failure due to an inability to maintain cardiac output

http://emedicine.medscape.com/article/150638-overview#a3
Pathophysiology  5

• Increased LV mass, increased LV systolic pressure, and prolongation of the systolic ejection phase all elevate the myocardial oxygen requirement, especially in the subendocardial region.

• Although coronary blood flow may be normal when corrected for LV mass, coronary flow reserve is often reduced, which results in myocardial ischemia.

• Angina results from a concomitant increased oxygen requirement by the hypertrophic myocardium and diminished oxygen delivery secondary to diminished coronary flow reserve, etc.
Heart changes

Normal and aortic stenosis' hearts: find difference

http://www.marvistavet.com/assets/images/aortic_stenosis.gif
Signs and symptoms: classic triad

- Chest pain: angina pectoris is typically precipitated by exertion and relieved by rest
- Heart failure: symptoms include paroxysmal nocturnal dyspnea, orthopnea, dyspnea on exertion, and shortness of breath
- Syncope: often occurs upon exertion when systemic vasodilatation in the presence of a fixed forward stroke volume causes the arterial systolic blood pressure to decline

Signs and symptoms: other 1

- Low values of systolic and pulse blood pressure
- Pulsus alternans
- Hyperdynamic left ventricle
- Soft or normal S1, diminished or absent A2, paradoxical splitting of the S2, accentuated P2, ejection click, prominent S4, the classic crescendo-decrescendo systolic murmur
Signs and symptoms: other 2

Pressure gradient between the left ventricle and aorta, suggesting aortic stenosis
Signs and symptoms: other 3

The murmurs of aortic regurgitation

Soft or normal S1, paradoxical splitting of the S2, the classic crescendo-decrescendo systolic murmur

Assessment of Left Ventricular Outflow Gradient
Aortic valve insufficiency/regurgitation
Aortic insufficiency/regurgitation (AI) is the leaking of the aortic valve of the heart that causes blood to flow in the reverse direction during ventricular diastole, from the aorta into the left ventricle.
Types

- **Acute**: the acute onset of aortic regurgitation is usually a medical emergency due to the inability of the left ventricle to quickly adapt to the rapid increase in end-diastolic volume caused by regurgitant blood.

- **Chronic**: the chronic aortic valve regurgitation develops over decades.
Causes 1

- Half of the cases of AI are due to the aortic root dilation, which is idiopathic in 80% of cases, but otherwise may result from aging, syphilitic aortitis, osteogenesis imperfecta, aortic dissection, Behçet's disease, reactive arthritis and systemic hypertension.

- In 15% the cause is innate bicuspidal aortic valve, while another 15% cases are due to retraction of the cusps as part of postinflammatory processes of endocarditis in rheumatic fever/infective endocarditis and various collagen vascular diseases.

https://en.wikipedia.org/wiki/Aortic_insufficiency
Causes 2

- Al has been linked to the use of some medications (fenfluramine, dexfenfluramine isomers, dopamine agonists, etc.)
- Other potential causes include Marfan's syndrome, Ehlers–Danlos syndrome, ankylosing spondylitis, etc.
Types of causes

Functional classification of aortic insufficiency (AI) with description of disease mechanisms

Pathophysiology

In aortic insufficiency (AI), when the pressure in the left ventricle falls below the pressure in the aorta, the aortic valve is not able to completely close, and this causes a leaking of blood from the aorta back into the left ventricle (regurgitating).

The percentage of blood that regurgitates back through the aortic valve due to AI is known as the regurgitant fraction.

https://en.wikipedia.org/wiki/Aortic_insufficiency
Pathophysiology 2

- The regurgitant flow causes a decrease in the diastolic blood pressure in the aorta, and therefore an increase in the pulse pressure.
- While diastolic blood pressure is diminished and the pulse pressure widens, systolic blood pressure generally remains normal or can even be slightly elevated.
- The volume overload causes left ventricular hypertrophy (LVH) and dilation.

https://en.wikipedia.org/wiki/Aortic_insufficiency
Heart changes

Normal and aortic insufficiency/regurgitation’ hearts: find difference

Main hemodynamics disturbances

The changes in aortic pressure (AP), left ventricular pressure (LVP) and left atrial pressure (LAP)
Symptoms

• Dyspnea on exertion, orthopnea
• Paroxysmal nocturnal dyspnea
• Palpitations
• Heart murmur
• Angina pectoris
• Fatigue, weakness
• Swollen ankles and feet (edema)
• Lightheadedness or fainting
• Cyanosis
• Circulatory shock
Physical examination

- Heart murmur that can be heard through a stethoscope
- Very forceful beating of the heart
- Bobbing of the head in time with the heartbeat
- Hard pulses in the arms and legs
- Low diastolic blood pressure
- Signs of fluid in the lungs

Dobutamine-stress echocardiography

A case of severe aortic valve regurgitation caused by an ascending aortic aneurysm in a young patient
Cardiac catheterisation

After adjustment for the systolic blood pressure level, the transvalvular gradient results in an ARI of 16.7 in a patient with moderate paravalvular aortic regurgitation PAR (A) and an ARI of 30.8 in a patient with trivial PAR(B).

Aortic Regurgitation Index

\[
ARI = \left( \frac{RR_{\text{dia}} - LVEDP}{RR_{\text{sys}}} \right) \times 100
\]

\[
ARI = \left( \frac{40 - 20}{120} \right) \times 100 = \boxed{16.7}
\]

\[
ARI = \left( \frac{50 - 10}{130} \right) \times 100 = \boxed{30.8}
\]
Mitral valve stenosis
Definition

Mitral stenosis (MS) is characterized by obstruction to left ventricular inflow at the level of mitral valve due to structural abnormality of the mitral valve apparatus.

Causes

• The most common cause is rheumatic fever
• Other causes: malignant carcinoid disease, systemic lupus erythematosus, rheumatoid arthritis, mucopolysaccharidoses of the Hunter-Hurler phenotype, Fabry disease, Whipple disease, methysergide therapy, nonrheumatic mitral annular calcification, etc.
Pathophysiology 1

• The normal mitral valve orifice area is approximately 4-6 cm$^2$; as the orifice size decreases, the pressure gradient across the mitral valve increases to maintain adequate flow.

• Patients will not experience valve-related symptoms until the valve area is 2-2.5 cm$^2$ or less, at which point moderate exercise or tachycardia may result in exertional dyspnea from the increased transmural gradient and left atrial pressure.

Pathophysiology 2

- Severe MS occurs with a valve area of less than 1 cm²; as the valve progressively narrows, the resting diastolic mitral valve gradient, and hence left atrial pressure, increases; this leads to transudation of fluid into the lung interstitium and dyspnea at rest or with minimal exertion.

- Hemoptysis may occur if the bronchial veins rupture and left atrial dilatation increases the risk for atrial fibrillation and subsequent thromboembolism.
Pathophysiology 3

- Pulmonary hypertension may develop as a result of (1) retrograde transmission of left atrial pressure, (2) pulmonary arteriolar constriction, (3) interstitial edema, or (4) obliterative changes in the pulmonary vascular bed.

- As pulmonary arterial pressure increases, right ventricular dilation and tricuspid regurgitation may develop, leading to elevated jugular venous pressure, liver congestion, ascites, and pedal edema.
Pathophysiology 4

• LVEDP and cardiac output are usually normal in the person with isolated mitral stenosis

• As the severity of MS increases, the cardiac output becomes subnormal at rest and fails to increase during exercise

• 1/3 of patients with rheumatic MS have depressed LV systolic function as a result of chronic rheumatic myocarditis
Heart changes

Normal and mitral valve stenosis’ hearts: find difference

Signs and symptoms

• Irregular pulse of atrial fibrillation
• Rise in jugular venous pressure
• Parasternal heave with right ventricular hypertrophy
• Loud first heart sound
• Opening snap, which disappears as the leaflets become rigid
Signs and symptoms 2

- Classic late diastolic murmur with presystolic accentuation
- Shortness of breath
- Fatigue or weakness
- Paroxysmal nocturnal dyspnea (cardiac asthma)
Signs and symptoms 3

Atrial fibrillation
Less common signs and symptoms

• Hoarseness and vocal cord paralysis
• Trouble swallowing
• Chest pain
• Skin color changes, such as pink to purple shades on the cheeks or a dark blue color on the body from reduced blood flow in the end stages of the disease
• Coughing up blood (Hemoptysis)
• Thromboembolism in later stages
• Ascites and edema and hepatomegaly (right-side heart failure)
Physical examination 1

- Jugular venous distension due to rise in jugular venous pressure (with coexistent tricuspid regurgitation)
- Irregular pulse of atrial fibrillation
- Parasternal heave with right ventricular hypertrophy
- Tapping apex beat (manifestation of a loud first heart sound)

http://www.learntheheart.com/assets/1/7/MS.png
https://en.wikipedia.org/wiki/Mitral_valve_stenosis
Physical examination 2

• Shift of heart dullness upward (left atrium) and to the right (right ventricle)

• The first heart sound is usually loud and may be palpable (tapping apex beat) because of increased force in closing the mitral valve

• If pulmonary hypertension secondary to mitral stenosis is severe, the pulmonic component of the second heart sound will become loud
Physical examination 3

• A mid-diastolic rumbling murmur with presystolic accentuation will be heard after the opening snap
• Signs of pulmonary hypertension
• Hepatomegaly
• Ascites
Physical examination

Auscultation

Selected laboratory studies 1

- Serum electrolyte levels
- Cardiac biomarkers
- Complete blood count

Doppler echocardiography

Transesophageal echocardiogram with continuous wave
Computed tomography
Pressure tracings in the LA and the LV in an individual with severe mitral stenosis. Blue areas represent the diastolic pressure gradient due to the stenotic valve.
Mitral valve
insufficiency/regurgitation
Definition

Mitral insufficiency/regurgitation (MI) or mitral incompetence is a disorder of the heart in which the mitral valve does not close properly when the heart pumps out blood; it is the abnormal leaking of blood backwards from the left ventricle, through the mitral valve, into the left atrium, when the left ventricle contracts, i.e. there is regurgitation of blood back into the left atrium.

https://en.wikipedia.org/wiki/Mitral_insufficiency
Types, causes

• Types: acute, chronic
• Causes:
  – the most common cause is mitral valve prolapse (MVP)
  – Other causes: ischemic heart disease, Rheumatic fever, Marfan's syndrome, Ehlers Danlos Syndrome, the dilatation of the left ventricle that causes stretching of the mitral valve annulus and displacement of the papillary muscles (dilated cardiomyopathy, etc.)

https://en.wikipedia.org/wiki/Mitral_insufficiency
The pathophysiology of MI can be broken into three phases of the disease process:

- the acute phase
- the chronic compensated phase
- the chronic decompensated phase
Pathophysiology 2

The acute phase:

- Acute MI (as may occur due to the sudden rupture of a chorda tendineae or papillary muscle) causes a sudden volume overload of both the LA and the LV.
- The regurgitant volume causes a volume overload and a pressure overload of the LA and the LV.
- The increased pressures in the LA may inhibit drainage of blood from the lungs and lead to pulmonary congestion.

https://en.wikipedia.org/wiki/Mitral_insufficiency
The chronic compensated phase

- If the MI develops slowly over months to years or if the acute phase cannot be managed with medical therapy, the individual will enter the chronic compensated phase of the disease.

- In this phase, the LV eccentric hypertrophy and the enlargement of the LA improve the drainage from the pulmonary veins, and patients may be asymptomatic and have normal exercise tolerances.
Pathophysiology 4

The chronic decompensated phase

• The ventricular myocardium is no longer able to contract adequately to compensate for the volume overload of MR, and the SV of the LV will decrease with decreased forward cardiac output

• The LV begins to dilate with a dilatation of the mitral valve annulus, which may worsen the degree of MI

• A decreased SV and no other cardiac abnormality should alert the physician that the MI may be in its decompensated phase

https://en.wikipedia.org/wiki/Mitral_insufficiency
Heart changes

Mitral valve insufficiency/regurgitation’ and stenosis hearts: find difference
Main hemodynamics disturbances

The changes in aortic pressure (AP), left ventricular pressure (LVP) and left atrial pressure (LAP)

http://www.cvphysiology.com/Heart%20Disease/HD005%20mitral%20regurgitation.gif
Symptoms

• The larger the LV, the more advanced is the MR

• Symptoms include:
  • Shortness of breath, which may later develop into shortness of breath at rest and at night
  • Fatigue and weakness
  • Edema (fluid buildup in the legs and feet, orthopnea, paroxysmal nocturnal dyspnea)
  • Heart palpitations (atrial fibrillation, which can lead to blood clots forming in the atrium)

Physical examination 1

- Asthenic body habitus
- Low body weight or body mass index (BMI)
- Straight-back syndrome
- Scoliosis or kyphosis
- Pectus excavatum
- Hypermobility of the joints (e.g., Marfan syndrome)
The 1st heart sound ($S_1$) may be soft (or occasionally loud); a 3rd heart sound ($S_3$) at the apex reflects a dilated LV and important MR; an $S_3$ that accompanies mitral regurgitation suggests a dilated left ventricle and progression to heart failure.
The cardinal sign of MR is a holosystolic (pansystolic) murmur, heard best at the apex with the diaphragm of the stethoscope when the patient is in the left lateral decubitus position.
Diagnostic tests

- Echocardiography
- Quantification of mitral insufficiency
- Cardiac magnetic resonance imaging
- Electrocardiography (ECG)
- Chest X-ray
- Cardiac catheterization

Echocardiography 1

Mitral Valve Regurgitation
(Mitral Insufficiency)

Mild  Moderate  Severe
Transesophageal echocardiogram: apical 4-chamber projection where small vegetations can be observed on both mitral valves (arrows); severe MR
Ischemic mitral regurgitation due to acute elongation of papillary muscle, appearing as mitral valve prolapse
Echocardiography 4

Color flow recording of a MR jet: flow convergence, vena contracta (VC), and jet area in the left atrium.
